There is a tool called HTTPX, which is used to check Subdomains are Active or Not and there are multiple methods to use this tool. We will see the simple method only.

Steps :

► Requirement:

► Enumerate/Collect all subdomains using tools like subfinder, assetfinder, Knockpy and haktrails, etc.

Run : `subfinder -d someweb.com -o subf.txt -v`

Run : `echo "someweb.com" | haktrails subdomains > haksubs.txt`

Run : `assetfinder -subs-only someweb.com > asset.txt`

► Add all Enumerated/Collected subdomains from different tools in different files into one file with unique subdomains, that may be *subdomains.txt*

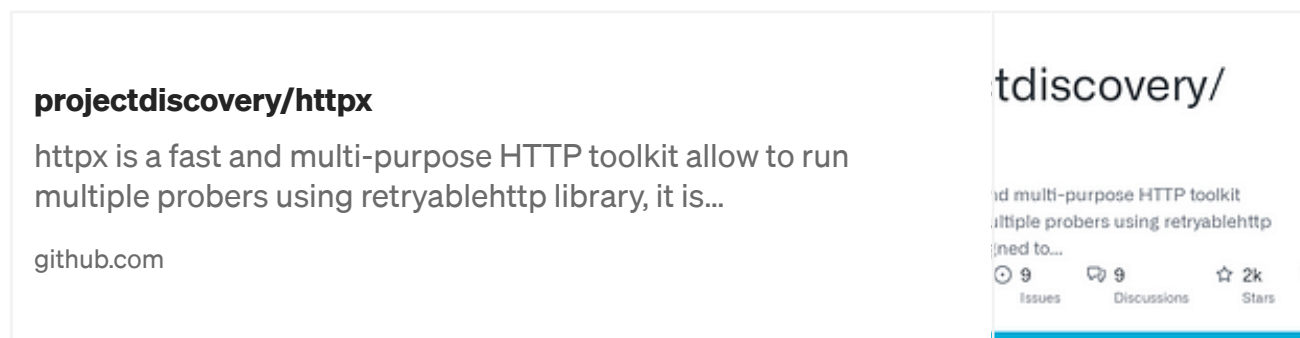

Run : `cat subf.txt haksubs.txt asset.txt | sort -u > subdomains.txt`

► Now, will check the identified subdomains are active or not -

Run : `httpx -l subdomains.txt -o activesubs.txt -threads 200 -status-code -follow-redirects`

► You'll able to see the active subdomains only, on which you can start finding bugs and all.
